SUMMARY

There are now 12 recently surveyed populations and one historical record of the sensitive annual plant *Clarkia rhomboidea* known in Montana. These are confined to the extreme northwestern part of the state in Sanders and Lincoln Counties. Sites are known on the Kootenai and Lolo National Forests and on state land. The species grows in undisturbed native habitat on steep, unstable, south facing slopes sparsely forested by Douglas fir and ponderosa pine. A few populations are found on road cutbanks and in logged areas. The primary threat to this species in Montana is encroachment of its open habitats by exotic weeds.

ACKNOWLEDGEMENTS

This project was made possible by a cost share agreement between the Kootenai National Forest and the Montana Natural Heritage Program. I give special thanks to Kootenai National Forest employees Leslie Ferguson, Anne Karsian, Lou Kuennen, Dan Leavell, and Mike Lolley and to Anne Dalton on the Lolo National Forest. At the Montana Natural Heritage Program special thanks go to Bonnie Heidel for coordination and technical contributions, Margaret Beer for data processing, and Cedron Jones for GIS mapping.

FIGURE 2. MAP OF *CLARKIA RHOMBOIDEA* DISTRIBUTION IN MONTANA 5
A. CLASSIFICATION

1. FAMILY: Onagraceae, The Evening Primrose Family

2. GENUS: Clarkia, a genus of about 33 species of annual herbs, 32 species endemic to western North America, and one to South America. In the past, Clarkia has been included in Oenothera and split between Clarkia, Eucharidium, Godetia, and Phaeostoma. The genus is divided into 10 sections which have a reticulate relationship connected by polyploid species of hybrid origin. (Lewis and Lewis 1955)

3. SPECIES: Clarkia rhomboidea Douglas. It is given the common name "common" clarkia (Hitchcock and Cronquist 1973), a misnomer for the species in Montana where it is rare, it is also called rhombic petaled clarkia. Synonyms (Lewis and Lewis 1955) include Oenothera rhomboides Lev., Phaeostoma rhomboides Nels., Clarkia gauroides Dougl. in Sweet, Godetia latifolia Nels. & Kennedy, and Phaeostoma atropurpureum Heller. Lewis and Lewis (1955) include Clarkia rhomboidea in their section Myxocarpa and have demonstrated that the species is an allotetraploid derived from a hybrid between C. mildredae and C. virgata, both species confined to California.

B. PRESENT LEGAL OR OTHER FORMAL STATUS

1. FEDERAL STATUS

a. U.S. FISH AND WILDLIFE SERVICE: none

b. U.S. FOREST SERVICE: Sensitive in Region 1 (U.S. Forest Service 1994)

c. BUREAU OF LAND MANAGEMENT: none

2. STATE: The Montana Natural Heritage Program ranks the species G4 and S1 (Heidel 1996) signifying that it is apparently secure rangewide but critically imperiled because of extreme rarity in Montana. Discovery of several populations in 1995 and 1996, some relatively large, would ordinarily be the basis for changing the rank to S2 except that populations of annuals are intrinsically unstable from year to year, and there are only a few known large populations in undisturbed native habitat that are likely to have high viability.
C. DESCRIPTION

1. GENERAL NONTECHNICAL DESCRIPTION: *Clarkia rhomboidea* is an herbaceous annual dicot ranging in size from less than six inches up to about three feet tall. Small plants may be unbranched and have only one flower, while larger plants may be branched and have several flowers. The elliptical shaped, stalked leaves are borne nearly opposite each other on the stems and there are usually branchlets with smaller leaves in the axils of the large leaves. The flowers are nodding in bud and become erect in bloom, are about the size of a dime and have four lavender-pink stalked petals and four green or purplish, reflexed sepals. The fruits develop below the petals and sepals, and when mature open by four valves and contain numerous small seeds. Figure 1 is a line drawing of the plant, and photographic slides of plants, including close-ups of the leaves, flowers, and fruits are provided in Appendix C.

2. TECHNICAL DESCRIPTION: Annual herb, 1-10 dm tall, simple or branched; leaves subopposite, puberulent to subglabrous, petiolate, the blades up to 6 cm long, 3.2 cm wide, ovate, ovate-lanceolate, or elliptic. Flowers short-pedicellate, nodding in bud, erect at anthesis, borne in bracteate terminal racemes; hypanthium 1-3 mm long; four sepals 5-9 mm long, green or purplish, reflexed at anthesis; four petals 6-12 mm long, 3-7 mm broad, clawed, the limb lanceolate to rhomboid, entire to obscurely 3 lobed, pinkish-lavender, sometimes with darker spots; eight stamens 1-4 mm long; ovary inferior, 4 loculed, stigma 4 lobed; fruit a straight or curved beaked capsule, 1-3 cm long, opening by 4 valves; seeds 1-1.5 mm, without hairs. (adapted from Lewis and Lewis 1955 and Welsh et al. 1987)

3. LOCAL FIELD CHARACTERS: *Clarkia rhomboidea* can be distinguished from *C. pulchella*, the only other species of the genus in Montana, by 1) lanceolate to elliptic, petiolate leaves vs. linear, sessile leaves of *C. pulchella*, 2) nodding flower buds vs. erect buds of *C. pulchella*, and 3) smaller, entire limbed petals vs. the larger petals of *C. pulchella* which have dramatically lobed limbs. *Clarkia rhomboidea* also resembles some species of *Epilobium*, from which it is distinguished by lacking a tuft of hairs on the tip of the seeds. *Clarkia rhomboidea* has larger flowers than *Epilobium minutum* and *E. paniculatum*, and smaller plants and flowers than *E. angustifolium*. Other species of *Epilobium* in Montana are plants of wetlands.

D. GEOGRAPHIC DISTRIBUTION

1. RANGE: Southern British Columbia south, east of the Cascades in Washington, but east and west of the Cascades in Oregon, to southern California, east to Montana, Utah, and Arizona (Hitchcock and Cronquist 1973 and Montana records).
Figure 1. Line drawing of *Clarkia rhomboidea* (from Hitchcock and Cronquist 1961)
2. MONTANA DISTRIBUTION

a. CURRENT SITES: There are 12 recently surveyed occurrences, all in northwest Montana in Lincoln and Sanders Counties. Peter Lesica made the first recent collection of the species on state land near Thompson Falls in 1989. The first occurrence on the KNF was found by Jack Triepke on the Cabinet district in 1993. In 1995 additional KNF populations were located on the Cabinet and Three Rivers districts and in 1996 an additional population was found on each district. The species was also found on the Lolo National Forest for the first time in 1996 by Anne Dalton. Table 1 gives land ownership and population estimates of all known Montana occurrences. Figure 2 is a map showing the approximate locations of Clarkia rhomboidea occurrences in Montana. Appendix A contains Element Occurrence Records giving precise locations and for all known sites in the state and topographic maps showing the locations are included in Appendix B.

Figure 2. Clarkia rhomboidea Distribution in Montana
b. HISTORICAL SITES: Lewis and Lewis (1955) list a *Clarkia rhomboidea* collection (Butler coll. # 5091) from Mt. Silcox, Montana (001). The location and date of the specimen are not known; this is apparently the basis for the inclusion of the species in Dorn's (1984) flora of the state. Lesica's rediscovery of *Clarkia rhomboidea* in Montana in 1989 was near Mt. Silcox, but it is not known if this is precisely the same location.

c. UNVERIFIED/UNDOCUMENTED REPORTS: none

d. LAND OWNERSHIP: Ten sites are Kootenai National Forest (KNF) lands, one is Lolo National Forest land, and one site is Montana State land.

e. AREAS SURVEYED BUT SPECIES NOT FOUND: I spent approximately eight field days in late June and early July, 1996 searching for new occurrences of *Clarkia rhomboidea*. My surveys were confined to the southwestern part of the Kootenai National Forest, and represent a sampling of potential habitat mostly distributed across the previously known range of the species on the Forest. The habitat surveyed was extremely steep with loose substrate, making access extremely difficult and at times dangerous, thus many gaps in the survey remain. A need for further survey was identified by Jack Triepke in the vicinity of the Lost Cabin Gulch occurrence (003); an attempt was made to access this population but was prevented by road washouts and posted private property. Lolo National Forest lands on the Thompson Falls district also remain as a large gap in survey for the species to date. The following areas on the Kootenai National Forest were identified by landtype, aspect, and vegetation as potential habitat for *Clarkia rhomboidea* and were surveyed but the species was not found:

Cabinet District

Beaver Creek: T23N R31W S32 SE 1/4, S33 S 1/2, T22N R31W S6 NW 1/4

Berray Mountain: T27N R33W S1 NE 1/4 (uphill from population found on lower slope)

Big Eddy Creek: T27N R34W S25

Blacktail Creek: T25N R32W S28 NW 1/4

Bull River: T26N R33W S3 SW 1/4, T27N R33W S24 NE 1/4

Kirby Gulch: T24N R30W S31 NE 1/4, S32 NW 1/4

Marten Creek: T25N R32 W S32 NE 1/4, S33 NW 1/4, S 28 SW 1/4

Pilgrim Creek: T26N R33W S28 SE 1/4

Pilgrim Creek (West Fork): T26N R33W S30 S 1/2
Vermillion River: T24N R31W S1 SW 1/4, S11 NW 1/4, S12 NE 1/4, S14 NE 1/4, T24N R30W S7 NW 1/4
Water Hill: T24N R31W S23 N 1/2, S24 SW 1/4
White Pine Creek: T23N R31W S14 NE 1/4, NW 1/4, S15 NE 1/4

Three Rivers District

Dry Creek: T29N R33W S9 NW 1/4
Keeler Mountain: T29N R34W S1 SE 1/4
Kootenai Falls: T31N R33W S12 SW 1/4, S13 NW 1/4, S14 NE 1/4
Lime Butte: T30N R34W S13 SE 1/4
Ross Creek Quarry: T28N R33W S7 NE 1/4
Spring Creek: T29N R33W S4 NW 1/4, NE 1/4 (forested slopes nearby known population on road cutbank)
Yaak River: T33N R33W S19 NW 1/4

E. HABITAT

1. ASSOCIATED VEGETATION: Lewis and Lewis (1955) describe the habitat of Clarkia rhomboidea across its range as "open, dry sites at the lower margins of the montane forest or sometimes in adjacent woodland." In Arizona it grows in oak woodland (Lewis and Lewis 1955) and in Utah it is associated with "mountain brush communities" (Welsh et al. 1987).

In Montana, Clarkia rhomboidea grows on slopes sparsely forested by Pseudotsuga menziesii and Pinus ponderosa and on the cutbanks of roads through these habitats. Vegetation at most sites is probably best classified as the Pseudotsuga menziesii/Physocarpus malvaceus habitat type (Cooper et al. 1991), but canopy cover is usually lower than described for that type and the dominant shrub is often Holodiscus discolor. Graminoid cover by Elymus spicatus often exceeds shrub cover and at least one site is a Pseudotsuga menziesii/Elymus spicatus (Agropyron spicatum) habitat type (Cooper et al. 1991). Many sites approach the scree habitat type (Cooper et al. 1991). These habitat types have low to moderate timber productivity and may present significant reforestation problems (Cooper et al. 1991). In spite of this they are sometimes logged because they often develop large old growth trees.

Montana Clarkia rhomboidea habitats are relatively stable disclimaxes controlled by topoedaphic and fire influences. Most sites have sparse to moderate undergrowth due to dry, unstable substrates which limit establishment of many native perennials. At least three Clarkia rhomboidea sites on the KNF have indications of past fires, including snags, deep fire scars on large Pinus ponderosa, and light burn on the downhill side of large Pseudotsuga menziesii.
Control of wildfires may result in increased cover by forest canopies, shrubs, and herbaceous perennials. These open habitats host many native annual plant species and are prone to invasions by exotic annual and perennial weeds. Establishment of noxious weeds may result in increased competition and soil stabilization. Wildfire control and weed infestations may allow vegetation succession to proceed and make the habitat unsuitable for *C. rhomboidea* and other native annuals.

At several sites *Clarkia rhomboidea* grows in needle litter just downhill from a large tree, a microhabitat which is shared with the native annual forb *Montia perfoliata* and the exotic annual grass *Bromus tectorum*. This microhabitat preference may be due to microclimatic influences, dispersal agents, or disturbance history (e.g. game bedding or fire) associated with understories of large trees.

At three Montana sites *Clarkia rhomboidea* grows with *Clarkia pulchella*, which is more abundant and has a broader distribution in the state. The two species have similar habitat preferences, and the latter may be used as an indicator of potential habitat for the rare species.

The following vascular plant species were observed at *C. rhomboidea* sites in Montana:

Native trees: *Pinus ponderosa*, *Pseudotsuga menziesii*

Native shrubs: *Acer glabrum*, *Amelanchier alnifolia*, *Hoidiscus discolor*, *Menziesia ferruginea*, *Paxistema myrsinites*, *Philadelphus lewisi*, *Physocarpus malvaceus*, *Prunus virginiana*, *Rosa gymnocarpa*, *Rosa woodsii*, *Salix scouleriana*, *Shepherdia canadensis*, *Symphoricarpos albus*

Native perennial forbs and subshrubs: *Achillea millefolium*, *Agoseris glauca*, *Apocynum androsaemifolium*, *Balsamorhiza sagittata*, *Calochortus sp.*, *Castilleja sp.*, *Fragaria vesca*, *Heuchera cylindrica*, *Lonicera ciliosa*, *Mahonia repens*, *Penstemon sp.*, *Penstemon wilcoxii*, *Phacelia heterophylla*, *Sedum lanceolatum*

Native perennial graminoids: *Carex geyeri*, *Calamagrostis rubescens*, *Elymus spicatus*, *Festuca idahoensis*, *Festuca occidentalis*

Native annual forbs: *Clarkia pulchella*, *Collinsia parviflora*, *Collomia linearis*, *Collomia grandiflora*, *Cryptantha affinis*, *Epilobium minutum*, *Epilobium paniculatum*, *Madi a minima*, *Madi a exigua*, *Microsteris gracilis*, *Montia perfoliata*, *Polygonum douglasii*
Native annual graminoids: *Festuca octoflora*

Native ferns: *Aspidopsis densa, Cryptogramma achrostichoides, Pteridium aquilinum, Woodia scopulina*

Exotic perennial forbs: *Centaurea maculosa, Dianthus armeria, Hypericum perfoliatum, Tragopogon dubius, Trifolium repens, Verbasum thapsus*

Exotic perennial grasses: *Phleum pratense*

Exotic annual forbs: *Arenaria serpyllifolia*

Exotic annual grasses: *Bromus tectorum*

Moss cover is essentially non-existent but cover by soil crustose lichens is conspicuous at some sites.

Photographic slides showing vegetation at undisturbed sites at Berray Mountain (011) and Rock Creek (007) are provided in Appendix C.

2. **TOPOGRAPHY:** All known Montana occurrences of *Clarkia rhomboidea* are in the Cabinet and Bitterroot Mountains on steep slopes with southerly aspects at elevations ranging from 2,400 to 4,200 feet (730-1,280 meters). Two populations (Spring Gulch .005 and Spring Creek .009) are at least partially on cutbanks of roads which cross these slopes. Populations are usually in mid-slope positions on slopes ranging from 35-80% with aspects ranging from south-southeast to southwest. Slope and aspect are dominant influences on the soils, microclimates, and vegetation of the sites. The sites were probably not directly affected by glaciation but mountain glaciers were present at higher elevations and continental glaciation extended south in the valleys below the most northern occurrences.

3. **SOIL RELATIONSHIPS:** In Montana, *Clarkia rhomboidea* grows in droughty, gravelly, poorly developed soils associated with steep south aspects with rock outcrops. On the KNF, the soils are classified as inceptisols and include map units 201, 353, 355, 502, 503, and 555 (Kuennen and Nielsen-Gerhardt 1995). The soils have a high fraction of gravel and small rocks weathered from metasedimentary rocks of the Belt Supergroup. At two sites which were sampled, the reddish argillites and quartzites of the Pritchard Formation (identified by L. Kuennen) make up a large part of the rock fraction; this is a dominant rock type in the area (Alt and Hyndman 1986). Wildfire control and invasion of the sites by exotic weeds may hasten soil development by stabilizing the substrate and adding organic matter.
4. CLIMATE FACTORS: Data from the climatological stations at Trout Creek Ranger Station and Thompson Falls (National Oceanic and Atmospheric Administration 1982) characterize the macroclimate of the Montana range of *Clarkia rhomboidea*. From 1951 to 1980 the monthly mean temperature normals ranged from 26.4 degrees F in January to 68.2 degrees F in July at Thompson Falls and from 24.1 degrees F in January to 65.0 degrees F in July at Trout Creek. Normal annual precipitation was 22.77 inches at Thompson Falls and 30.49 inches at Trout Creek. July is the hottest and driest month of the year, coinciding with the flowering period of *Clarkia rhomboidea*. Peak precipitation at both stations is during the winter months in the form of snow, but abundant rainfall occurs in both the fall and the spring, both possible periods for seed germination. Annual precipitation at Trout Creek is the second highest of stations in Montana.

The Cabinet and Bitterroot Mountains receive high precipitation, but the population sites are droughty by mid-summer. The south facing slopes are hot and dry compared to adjacent aspects, creating habitats with sparse vegetation. Annuals are adapted to these conditions by remaining dormant, as seeds, during the driest part of the season. Lewis and Lewis (1955) found that high temperatures promote flowering in *Clarkia* species, but that seed germination requires cooler temperatures. The tendency of plants to grow under large trees may be related to microclimate influences on seedling germination and survival. Canopies reduce rainfall but also reduce evaporative loss at ground level, they reduce solar radiation in the daytime and also reduce radiation loss at night; these interacting effects result in a microsite which is relatively droughty and free from competition but also with relatively stable moisture and temperature regimes. Litter accumulation under the trees may also influence soil surface moisture and temperature.

F. POPULATION DEMOGRAPHY AND BIOLOGY

1. PHENOLOGY: In Montana, *Clarkia rhomboidea* has been observed flowering from mid-June to mid-August. Peak flowering is probably in early July at most sites in most years, but an indeterminate inflorescence may result in prolonged flowering in favorable years. Small plants were the first to flower in populations observed in 1996. *Clarkia rhomboidea* blooms at about the same time as *C. pulchella*, or slightly earlier, and the more common species can be used as an indicator for timing surveys for the rare plant. Fruit have been observed as early as July 1. One population visited on October 1, 1996 had plants with dehiscent fruits and most seeds dispersed, except for a few in the bottoms of the uppermost capsules of large plants.

It is not known when seed germination takes place in Montana. Lewis and Lewis (1955) studied species of *Clarkia*, including *C. rhomboidea*, in the garden in Los
Angeles, California and made some generalizations concerning phenology of the genus. Seeds germinated in November and flowering occurred in April-May depending on the species. The plants were thus grown as winter annuals. Seeds planted in January or February produced smaller, later flowering plants. Controlled experiments showed that flowering was promoted by long daylight and high temperatures, but seed germination was prevented by high temperatures. In England they grew species of Clarkia as summer annuals. Some seeds of predominantly fall germinating annuals may germinate in spring (Nilsson 1995), and this characteristic is likely to be under selection pressure. It is possible that, in nature, Clarkia rhomboidea behaves as a winter annual over some of its range and as a summer annual in other areas. Because of severe winters, there may be selection for spring germination in Montana. This hypothesis could be tested by conducting searches for seedlings in both fall (October-November) and spring (March-April). Seedlings were not found in the Clarkia rhomboidea population area at Berray Mountain when visited on October 1, 1996. Timing of seed germination may have management implications in timing weed control or prescribed burns.

2. POPULATION SIZE AND CONDITION: Reported population numbers in Montana range from a couple to over a thousand plants. The Rock Creek (007) occurrence is the largest reported with estimates of 1000-1500 plants in six subpopulations covering 125 acres; many particularly large plants were observed in this population. “Thousands of plants” were also reported at Spring Gulch (005), but most plants are confined to a small area of road cutbank. At some sites only a few plants were found in spite of extensive surveys. These numbers do not include the number of seeds which remain dormant or the number of seedlings which die. Most populations censused in 1995 and 1996 had similar number of plants in both years. This may indicate that climate in both years was favorable for the species; both years had abundant moisture early in the growing season.

I could not relocate the Noxon Reservoir (010) occurrence in 1996, originally found by Mike Leigh in 1995 and estimated to have over 500 plants. It is possible that I did not look in the right location or that the population has undergone drastic decline or extirpation. The habitat is very weedy, and competition may have interfered with seed production or germination and survival.

Populations of annuals often undergo dramatic fluctuations in size from year to year. Lewis (1962) reported that peripheral populations of Clarkia species are subject to extinction or near extinction in climatically unfavorable years and this phenomenon has played a role in speciation of the genus. Fluctuations in size of Montana Clarkia rhomboidea populations and their relationship to climatic fluctuations has not been determined or studied.
3. REPRODUCTIVE BIOLOGY: \textit{Clarkia rhomboidea} is a predominantly self-pollinating allotetraploid annual. It has small flowers with the style receptive at anthesis and proximal to the stamens, unlike its outcrossing diploid parents \textit{C. mildrediae} and \textit{C. virgata} which have protrandrous flowers with the style held away from the stamens (Lewis and Lewis 1955). Bees have been observed visiting the flowers in Montana and may facilitate some cross pollination. Plants commonly have three to five flowers.

A single capsule is estimated to produce an average of 50 seeds (Lewis 1953, and Montana specimens). The small seeds have no known specialized dispersal mechanism but may be dispersed by birds, mammals, water, or disturbance of the unstable scree substrate. The occurrence of \textit{Clarkia rhomboidea} along trails at some sites is consistent with seed dispersal by game although herbivory of fruits has not been observed. Lewis (1962) reported dispersal of intact fruits of \textit{Clarkia} species by rodents. The fruits of \textit{Clarkia rhomboidea} become soft and slimy as they mature (Lewis and Lewis 1955), and this could play a role as an animal deterrent or attractant.

The role of a seed bank in the population biology of \textit{Clarkia rhomboidea} is not known. Lewis (1962) found no evidence of dormancy in seeds of \textit{Clarkia} species and believed this is why no desert members of the genus have evolved. Seeds were found to be viable for up to five years, but germinate freely. One possible short term dormancy mechanism may be retention of a few seeds overwinter in the erect capsules (Lewis 1962); a few seeds were found remaining in capsules at Berray Mountain (011) in October 1996.

As a species, \textit{Clarkia rhomboidea} has become more widespread (more reproductively successful) than either of its diploid, outcrossing parents. This may be in part due to its genetic and breeding systems. Polyploidy can impart heterostyly and homeostasis to an organism which may have adaptive value and is a means of breeding true a desirable hybrid genotype (Grant 1981). There is a correlation between alloplody and autogamy (selfing) in annual plants (Grant 1981). The ability to self also confers colonizing advantage by allowing a population to be founded by introduction of a single seed.

G. POPULATION ECOLOGY

1. BIOLOGICAL INTERACTIONS

a. COMPETITION: \textit{Clarkia rhomboidea} grows in open habitats where competition from native perennials is limited by a harsh, unstable environment. In Montana habitats with few introduced plants it coexists with a number of native annuals, but overall cover and biomass are very
small. Differences in annual plant species dormancy strategies and adaptations to small scale disturbance may explain their coexistence in patchy landscapes (Lavorel et al. 1994).

Introductions of exotic species may increase cover and biomass of sites, and increase competition from biennial and perennial forbs. Some Montana noxious weeds are highly adapted to southwest facing slopes with open vegetation and loose substrate. Much of the potential habitat identified and surveyed in 1996 that turned out not to have *C. rhomboidea* was heavily infested by weeds. Weeds are present at most *C. rhomboidea* sites, but infestations were light in most populations surveyed in 1996. The species has been observed in Montana growing in close association with high densities of cheatgrass (*Bromus tectorum*) at Berray Mountain (011) and spotted knapweed (*Centaurea maculosa*) at Spring Creek (009) but long term effects of competition from weeds has not been studied. At Spring Creek the co-occurrence with knapweed was observed by Leslie Ferguson in 1995, but this relationship was not apparent to the author in 1996. The population of *Clarkia rhomboidea* at Noxon Reservoir (010) was reported to consist of several hundred plants in 1995, but no plants were found in 1996 when this extremely weedy habitat was resurveyed by the author. It is possible that *C. rhomboidea* was excluded from the immediate areas by competition from knapweed. Spotted knapweed has been shown to interfere with growth and survival of *Lesquerella carinata var. languida*, a short-lived perennial of open south slopes in Granite County, Montana, and infestations of the weed are thought to be the major threat to that rare species (Greenlee 1994, Vanderhorst 1995). Competition for water and other nutrients is the most likely mechanism for these adverse effects.

b. **HERBIVORY:** Herbivory has not been reported in Montana, but the occurrence of *Clarkia rhomboidea* along trails may indicate seed dispersal by game. The mucilaginous fruits may serve as a deterrent or attractant to herbivores. The habitats away from trails on steep, unstable slopes are little visited by game.

**H. ASSESSMENT AND MANAGEMENT RECOMMENDATIONS**

1. **THREATS TO CURRENTLY KNOWN POPULATIONS:** The most pervasive and probably most severe threat to *Clarkia rhomboidea* populations in Montana is encroachment of its habitat by exotic weeds. Weeds are found at most Montana occurrences, but at present, sites with intact native vegetation have only light to moderate infestations. The slopes which host the large *Clarkia rhomboidea* population at Rock Creek (007) are almost weed free. It is not known if *Clarkia*
rhomboidea once inhabited other weedy habitat where it is absent today. Unlike habitats with high canopy and ground cover, open habitats are predisposed to colonization by exotic weeds without human caused disturbance. Weed infestations often proceed uphill from disturbed areas onto undisturbed slopes with open vegetation.

The primary threats from logging and road building are indirect, from increased spread of weeds. Removal of large trees may also eliminate the preferred microhabitat of Clarkia rhomboidea under their canopies. All known populations on the Kootenai National Forest are within management areas 10 and 11 (big game winter range). All of the known populations with undisturbed native plant communities (Berray Mountain .011, Camp Creek .013, Grimes Gulch .004, Lost Cabin Gulch .003, Rock Creek .007, West Fork Elk Creek .008) are in management area 10 which is considered unsuitable timberland, probably because of steepness and low productivity. Road building through these habitats and logging of adjacent slopes is likely to result in introductions of exotic weeds which may threaten the rare plant populations and reduce useable forage for big game. Populations in disturbed habitats (Green Mountain .006, Noxon Reservoir .010, Spring Creek .009, Spring Gulch .005) are all within management area 11 which is deemed suitable timberland, and the sites are along roads or in logged areas. The occurrence of C. rhomboidea at these sites is likely to be ephemeral and related to the disturbance event. Clarkia rhomboidea has not been found in forests with high canopy cover.

Control of wildfires may also pose a long-term threat to populations of Clarkia rhomboidea by allowing canopy closure and vegetation succession to proceed. There are indications that steep south facing slopes are naturally prone to frequent low intensity surface fires which may reduce litter and duff, and kill lower layer perennials and tree seedlings but leave large trees.

2. MANAGEMENT PRACTICES AND RESPONSE: Clarkia rhomboidea has been observed growing on road cutbanks and on previously logged slopes. Two of the Montana occurrences (Spring Creek .009, Spring Gulch .005) are primarily on cutbanks and the former is apparently confined to the cutbank. These are usually treated as D-ranked Element Occurrences because they do not represent the species in stable habitats and thus do not contribute directly to its conservation. Relatively large populations of C. rhomboidea were reported in 1995 from Green Mountain (006) and Noxon Reservoir (010) in areas which were previously logged and had heavy weed infestations. The Noxon Reservoir population could not be relocated by the author in 1996 and may have undergone a decline or been extirpated. The species has not been found on slopes with closed canopies, thus its occurrence in recently logged areas is likely to be a recent and ephemeral phenomenon. Elsewhere it has been seen growing on ground
recently disturbed by game and erosion. Evidence of past fire is present at three sites or more. The species is adapted to colonizing disturbed sites, however, data on its persistence and interactions with exotic weeds at these sites is lacking.

3. MANAGEMENT SUMMARY: It is recommended that Forest Service Region 1 sensitive status and Montana Natural Heritage Program S1 rank be retained for *Clarkia rhomboidea*. Although ten occurrences have been discovered in the last two years, only three populations in Montana (Berray Mountain .011, Grimes Gulch .004, Rock Creek .007) consist of more than 100 plants in natural habitat, and its persistence in weedy, disturbed habitats has not yet been demonstrated. If it is found to be abundant on the Lolo National Forest where survey gaps remain, and is proved to persist on road cutbanks and in weedy clearcuts, then delisting as sensitive may then be appropriate.

The nature of threats to *Clarkia rhomboidea* populations are long term and indirect, thus project clearances and assessments which consider only the area of project activity are inadequate. For example, the proposed Rock Creek mine is not likely to directly affect the nearby population of *C. rhomboidea*, but increased ground disturbance and traffic of large trucks is likely to result in weed infestations which may then spread to the population site uphill. Population downtrends resulting from weed encroachment and vegetation succession are likely to be slow and will not be apparent without long term monitoring. Because the threats are indirect, proactive efforts may be required to avert population declines.

Focused weed control is needed in population areas in native habitat with light infestations (Rock Creek, Berray Mountain) and efforts should be made to reduce weed seed sources from adjacent and nearby disturbed habitats. Weeds should be controlled with methods which do not harm the rare species or other native plants (hand pulling or selective backpack spraying), and should be timed for maximum effectiveness and minimum impact. Human disturbance (i.e. walking, herbicide use, etc.) in population areas should be minimized when plants are in stages of active growth. Proposals for management activities (e.g. timber sales, road building, vehicle travel, mining) in the vicinity of *Clarkia rhomboidea* populations must address the threat of increased moderate distance dispersal of noxious weed seeds.

At least some of the *Clarkia rhomboidea* populations in Montana grow in habitats influenced by past fires and fire may be important for maintaining habitat and/or creating new habitat for the species. Natural and controlled burns should be managed to protect and improve habitat for *C. rhomboidea*. Fires occurring in or near populations should be monitored to determine seed bank mortality, colonization, and recolonization of burned areas by *C. rhomboidea* and other
native and exotic plants. Large populations should be protected from wildfires which threaten the entire population area, but some patchy, light surface fires may be allowed in population areas so that fire relations can be studied.

Additional research is proposed to define biological evaluation standards for *Clarkia rhomboidea*. We recommend: 1) three or more permanent ecodata plots be established at population centers at Rock Creek (at least two plots) and Berray Mountain (at least one plot) to document long term population viability, weed invasion, and vegetational succession at these undisturbed sites. 2) a permanent belt transect (Lesica 1987) be established at the population center along the trail at Berray Mountain with revisits made the following October and May to search for seedlings. Determining timing of seedling establishment is important for timing conservation management efforts as well as activities which may have adverse effects on populations. 3) Once timing of seedling establishment is determined, an experimental burn and control should be considered in the extensive Rock Creek population area, designed to have the least impact on germination, to make initial evaluations on the effects of fire. This is needed to establish prescribed burn and wildfire control standards to complement species conservation. 4) Revisit the known sites with disturbed habitats (Calvin Wilson Ranch .002, Green Mountain .006, Noxon Reservoir .010, Spring Creek .009, Spring Gulch .005) to determine if populations are persistent in these habitats.

Montana's *Clarkia rhomboidea* populations are peripheral to the rather broad contiguous range of the species and may be evolutionarily important because they face ecological extremes and may be subject to high selection pressures. Lewis (1962) hypothesized a mode of speciation in *Clarkia* involving "catastrophic selection", in which peripheral populations may undergo near extinction, followed by regeneration by one or a few adapted individuals with aberrant genotypes. Hybridization, chromosome anomalies, polyploidy events, and the annual habit have allowed rapid, "quantum" speciation to occur in *Clarkia* (Grant 1981, Lewis and Lewis 1955, Lewis 1962). Although polyploidy may be seen as a deterrent to speciation events (Grant 1981), the occurrence of hexaploid species in the genus demonstrates the potential for future evolution in the lineage of *C. rhomboidea* and the peripheral populations in Montana, even small ones, may play an important role in this process.

The habitats occupied by *Clarkia rhomboidea* are relatively stable disclimaxes resulting from topoedaphic and fire influences (Cooper et al. 1991, Pfister et al. 1974). Such "pioneer" habitats have been sites where rapid speciation of many annual plants has taken place (Steebns 1974). Another annual which is rare in Montana and which shares many of the genetic, evolutionary, and ecological traits of *C. rhomboidea* is *Madia minima*. This species, a Montana Species of Special Concern ranked S1 (Heidel 1996), was found in 1996 near a previously reported
Clarkia rhomboidea site and is known from a few other nearby sites. Preservation of habitat for Clarkia rhomboidea will also benefit other native annual species. However, open habitats are presently threatened by introduction of adapted exotic species and interference with naturally occurring ecosystem processes such as fire. These indirect human-caused effects may result in canopy closure and soil stabilization and development, thus allowing vegetation succession to proceed, closing the habitat for pioneer annuals. Maintaining native vegetation and rare plants in open habitats is a major challenge which will require proactive efforts and looking beyond project boundaries.

Location: DRIVE CA. 8 MILES NORTHWEST OF PLAINS ON HWY 200 TO THE WEEKSVILLE TUNNOFF ONTO FS RD 887. GO 2.8 MILES TO JUNCTION WITH FS RD 18253, GO LEFT AT FIRST THEN IMMEDIATELY RIGHT ON FS RD 18253. BEST PARKING IS .35 MILES NORTH. PARK AND GO UP RIDGELINE BETWEEN TEPEE CREEK AND WEEKSVILLE CREEK, .2 TO .3 MILE UP GAME TRAIL. ABOVE LARGE ROCK OUTCROP.
Element occurrence data: EIGHT PLANTS, 20% IN FLOWER, 80% VEGETATIVE ONLY; SMALL SWEAT BEES WERE OBSERVED VISITING BOTH CLARKIA RHOMBOIDEA AND CLARKIA PULCHELLA BLOSSOMS.
General site description: OPEN, EXPOSED, ROCKY, VERY DRY LOWER RIDGE LINE. SOILS TYPIC USTOCHREPTS - ROCK OUTCROP COMPLEX, STREAM BREAKLANDS. ASSOCIATED PLANT SPECIES INCLUDE AGROPYRON SPICATUM, PURSHIA TRIDENTATA, EPILOBIUM SPP., CLARKIA PULCHELLA, AMELANCHIER ALNIFOLIA, PHYSOCARPUS MALVACEUS, PSEUDOTSUGA MENZIESII, PINUS PONDEROSA, BALSAMORHIZA SIGITATA, FESTUCA OCCIDENTALIS, FESTUCA IDAHOENSIS, PENSTEMON SPP., ACHILLEA SPP., COLLOMIA GRANDIFLORA AND COLLINSIA PARVIFLORA.
Land owner/manager: LOLO NATIONAL FOREST, PLAINS/THOMPSON FALLS RANGER DISTRICT
Comments: CLARKIA RHOMBOIDEA SEEDS WERE POSSIBLY CARRIED TO THE SITE BY DEER OR OTHER WILDLIFE - THIS SMALL POPULATION IS ON A GAME TRAIL, WHILE MUCH OF THE SURROUNDING AREA SUPPORTS C. PULCHELLA. EVIDENCE OF DISTURBANCE INCLUDES LOGGING DEBRIS, BARE SOIL OF GAME TRAILS, ROADS ABOVE AND BELOW SITE AT SOME DISTANCE.
Information source: SENSITIVE PLANT COORDINATOR, LOLO NATIONAL FOREST, BUILDING 24, FORT MISSOULA, MISSOULA, MT 59801.

MONTANA NATURAL HERITAGE PROGRAM
Element Occurrence Record

Scientific Name: CLARKIA RHOMBOIDEA
Common Name: COMMON CLARKIA
Global rank: G4  Forest Service status: SENSITIVE
State rank: S2  Federal Status:
Element occurrence code: PDONA050X0.013
Element occurrence type:
Survey site name: CAMP CREEK
EO rank: C
EO rank comments: FEW PLANTS, EXTREMELY HOT SITE, RELATIVELY FEW WEEDS.
County: LINCOLN
   USGS quadrangle: CROWELL MOUNTAIN
Township: Range: Section: TRS comments:
030N 033W 33 SW4NW4
   Precision: S
   Survey date: 1996-07-13  Elevation: 2920 - 3280
First observation: 1996-07-13  Slope/aspect: 60-80% / SOUTH
Last observation: 1996-07-13  Size (acres): 1

Location: FROM TOWN OF BULL RIVER, GO WEST ON HWY 200 CA. 1.5 MILES, THEN NORTH ON 56 CA. 21 MILES ALMOST TO THE TOWN OF LITTLE JOE. FROM HWY 56, GO UP FS RD 691 CA. 1 MILE TO A BRIDGE. POPULATION IS ON STEEP ON SOUTH-FACING SLOPES TO THE NORTH.

Element occurrence data: 10 PLANTS COUNTED; 1 SUBPOPULATION; 70% IN FRUIT, 30% IN FLOWER, MATURE FRUIT PRESENT.

General site description: OPEN, DRY MIDDLE SLOPE, GRAVELLY-SANDY SOILS, BELT SERIES PARENT MATERIAL. PSEUDOTSUGA MENZIESII/ELYMUS SPICATUS HT, WITH HOLODISCUS DISCOLOR, PINUS PONDEROSA, POLYGONUM SP., AMELANCHIER ALNIFOLIA, MAHONIA REPENS.

Land owner/manager: KOOTENAI NATIONAL FOREST, THREE RIVERS RANGER DISTRICT

Comments: FIRE SCARS ON LARGE PINUS PONDEROSA; PLANTS ARE GROWING IN DISTURBED SOIL.

Information source: VANDERHORST, J. [BOTANIST]. P.O. BOX 1026, TROY, MT 59935.
